

## Stephen Soos – Bio

Stephen Soos is the founder, architect, and sole developer of Wnode, a sovereign, zero-trust compute platform built under circumstances that would have broken most people. His journey to Wnode did not begin in a lab, a venture studio, or a Silicon Valley accelerator. It began in a freezing Ukrainian winter, under martial law, with 2–4 hours of electricity a day, no running water, and the constant threat of drones and shelling.

After four years of enduring the war, Stephen and his family fled Ukraine in early 2026 with only what could fit in their small car. Their savings were trapped by capital controls. Their home was left behind. They arrived in Hungary with almost nothing, sleeping on a sofa, rebuilding life from zero. And in that moment of collapse, Stephen began building Wnode.

With no capital and no modern hardware, he assembled a “potato stack” of machines starting with a Lenovo M700 ThinkCentre with 12GB RAM, a Dell T1500 he re-engineered to accept a tiny GPU, and several broken laptops he repaired using parts scavenged from local markets. These machines crashed constantly. His AI tools lost context, froze, or hallucinated at critical moments. But Stephen worked from 1am to 5pm every day, driven by a mission that had crystallised during the war. The world needs a sovereign, decentralised compute layer that does not depend on fragile infrastructure or centralised power.

Stephen is no stranger to building under pressure. In the 80s he built and sold early computers. In the 90s he created one of the UK’s first ecommerce sites, then helped Xerox connect digital printers into an early cloud-like system that enabled same-day beachside newspaper printing. He built the UK’s first print e-procurement platform. In the 2000s he designed medical hardware, built Chinese supply chains, and created full-stack treatment ecosystems that scaled to seven-figure revenues and public listings. He built a 12-clinic gynecological network in 12 months using early AI orchestration, treating over 30,000 women and achieving national media coverage without spending a penny on advertising.

But Wnode is different. It is the culmination of everything he has learned over the years from systems architecture, AI orchestration, governance design, and the belief that decentralisation must serve everyday people, not hyperscalers.

Stephen's mission is bold: connect billions of existing devices into the world's largest compute layer, eliminate unnecessary datacenters, reduce global e-waste, and create a new income stream for anyone with a spare device. He believes compute is the emerging global economy, and that Wnode can become the sovereign layer that powers Earth, space, and eventually the Moon.

Wnode was not built in comfort. It was built in adversity, on potatoes and determination. And that is exactly why it will endure.
